Anemia in CKD – Updating the Definitions of Two Iron States

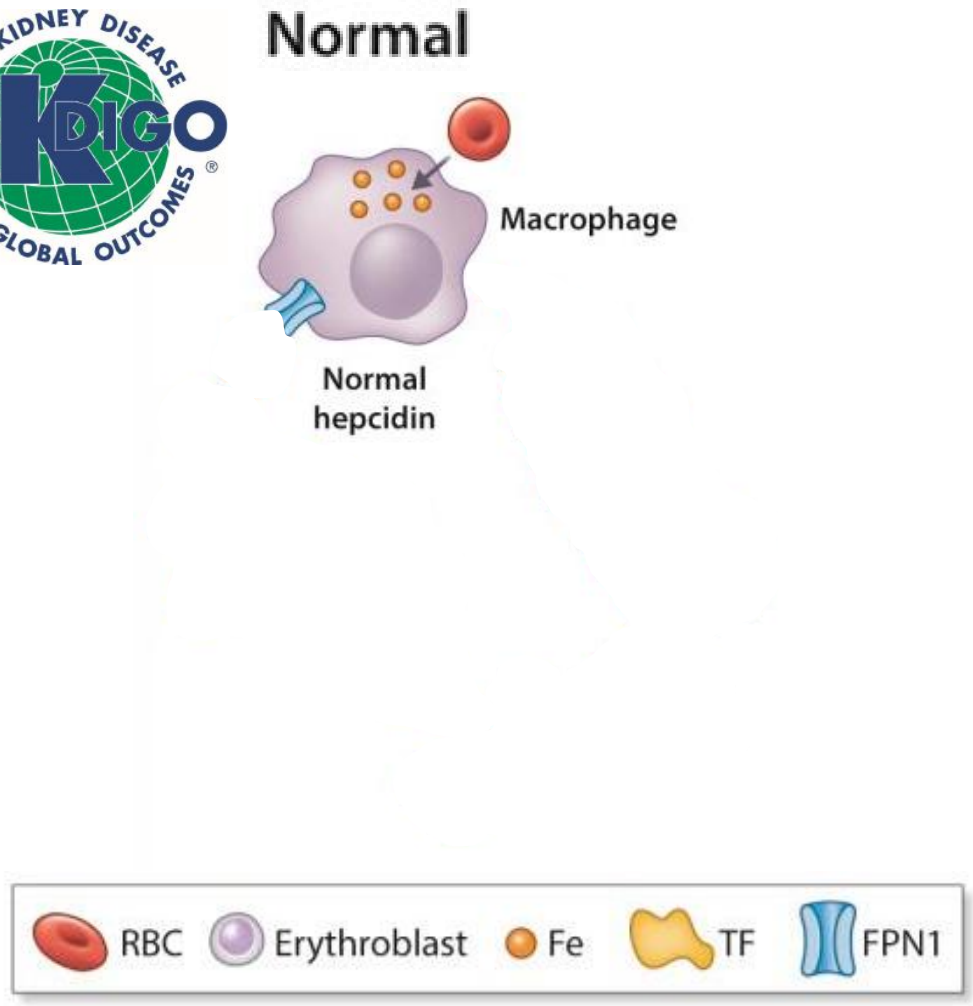

Figure 4 | Systemic movement of iron in different iron-related states.

Why 'One Size Fits All' No Longer Works

Table 1. Serum biomarkers for iron deficiency anemia in CKD

Name	Measures (U)	Relation to Iron Deficiency	Treatment Target[a]	Predicts Response to IV Iron	Sensitivity/ Specificity for Iron Deficiency[b]	Drawbacks
Ferritin	Level of ferritin in the blood (ng/dl)	Decreases (<100 ng/ dl diagnostic in nondialysis-	Uncertain[c]	Not reliable	<100 ng/dl: 35%/ 78%[31] <200 ng/dl: 41%/	Acute-phase reactant, elevations not solely related to iron status
		diagnostic in CKD)			27%[42]	
TSAT	Amount of iron bound to transferrin compared with total body stores (%iron/ TIBC)	Decreases (<20% diagnostic)	30%–50%	<30% Predictive	<20%: 63%/80%[21]	TIBC affected by inflammation and malnutrition
CHr	Absolute amount of Hg[illegible] re[illegible]	Not reflective of [illegible]	Not [illegible]	<29 pg predictive, [illegible]	57%/93%[31]	Time sensitive to [illegible]n of [illegible]tes
HRC%	Concentration of Hgb in RBCs (% relative Hgb content relative to RBC size)	Not reflective of stores	Not established	>6% predictive	82%/95%[31]	Must be measured within 6 h of collection
sTfR	Transferrin receptors shed from the RBC surface	May increase, can potentially note iron stores	Not established	>1.5 mg/L predictive	81%/71%[31]	Less reliable than CHr and HRC%, may rise in the setting of EPO
Hepcidin	Level of hepcidin in blood	Increases	Not applicable	Not reliable	Not applicable	—
Plasma NGAL	Level of NGAL in blood (ng/ml)	Increases	Not established	≤394 ng/ml	84%/50%[42]	—

TIBC, total iron binding capacity.
[a]Thresholds take into account current evidence and are recommended based on these data.
[b]Sensitivity/specificity measurements are best estimates, but comparisons across biomarkers are difficult because most studies were done in sample sizes of <100 patients and used different standards of comparison or diagnostic criteria (*e.g.*, bone marrow stores versus response to iron).
[c]Current recommendations 200–800 ng/dl and consider supplementation based on risk-benefit analysis for values ≥800 ng/m.

Traditional thresholds (TSAT, Ferritin) oversimplify biology

CHr (RET-He) and %HRC reflect real-time supply

Elizabeth Katherine Batchelor et al. JASN 2020;31:456-468

UK kidney association clinical practice guideline 2025

Guideline 2.2.2

We suggest that to define functional iron deficiency (FID) ("iron restricted erythropoiesis"), a TSAT < 20% in people with NDD-CKD or maintained on PD, and in those receiving HD be used. Normal or high serum ferritin values do not exclude iron deficiency, as it could be due to other causes such as infection or inflammation. (2B)

Rationale

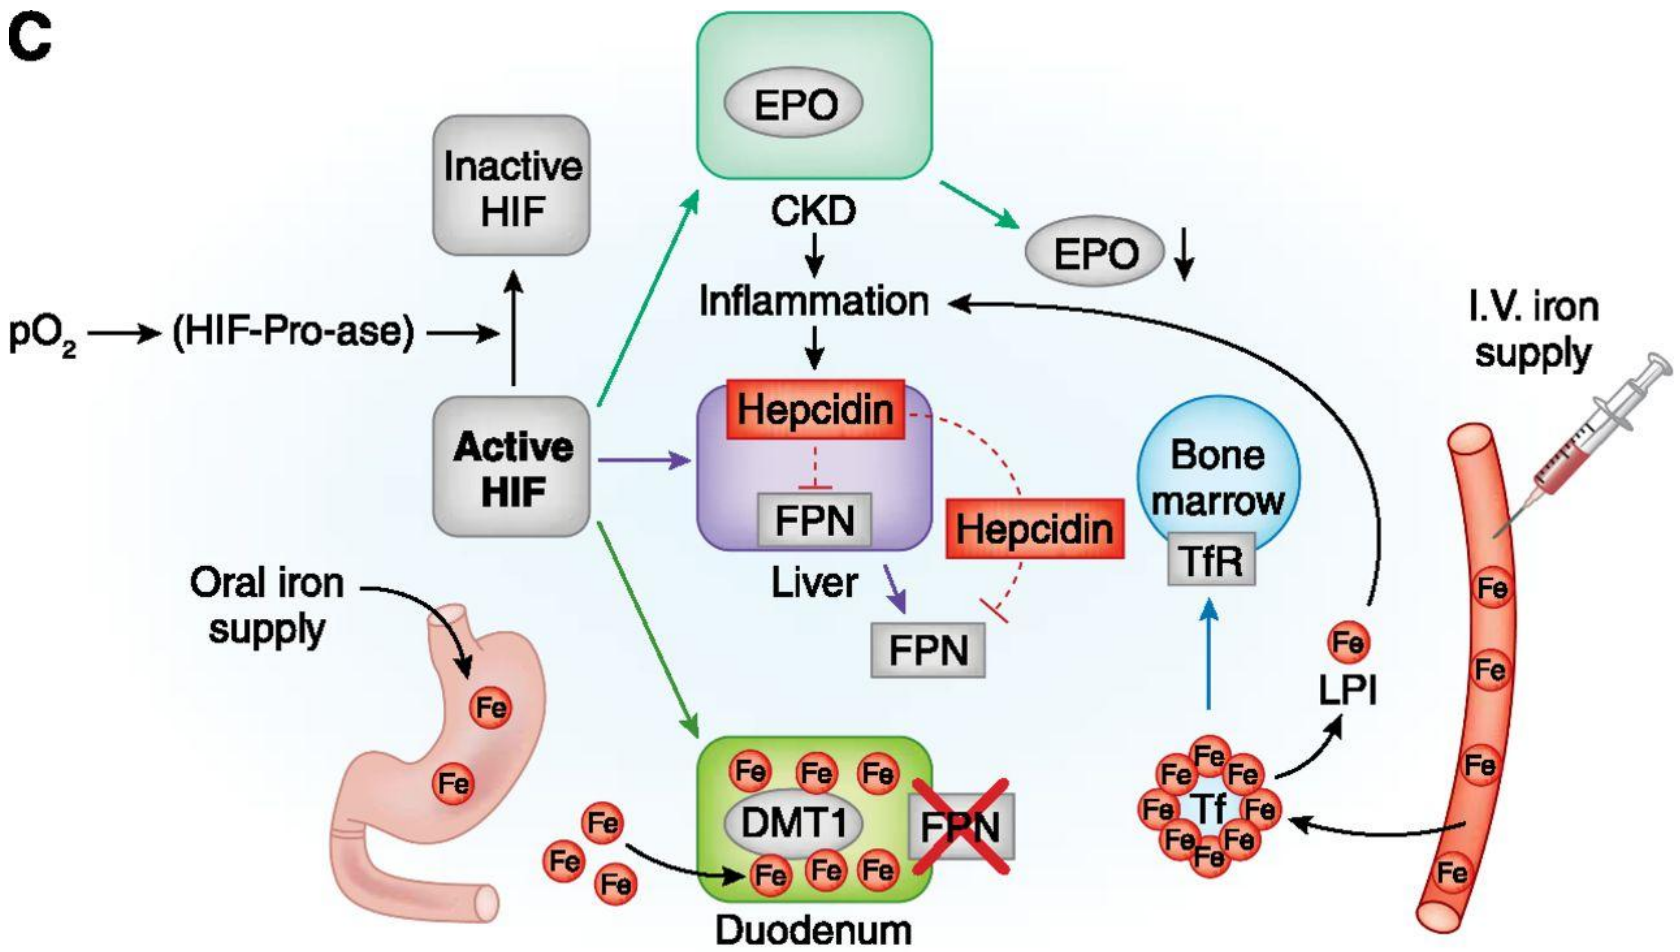
Iron is required for production of new red cells. Iron must be supplied to the erythropoietic tissue at an adequate rate, particularly if stimulated by ESA or HIF-PHI therapy.

•For people with CKD on dialysis (DD-CKD), percentage of **HRC > 6%,** or **CHr/RET-He < 31 pg** are ideal test to assess iron status.

•If these tests are not available or the person has thalassaemia or thalassaemia trait, a combination of transferrin saturation (less than 20%) and serum ferritin measurement (less than 100 mcg/L) could be a suitable alternative

Bhandari *et al. BMC Nephrology* (2025)

Iron Therapy Challenges for CKD Anemia



FPN: ferroportin

Locatelli F et al. CJASN 11:1269–1280, 2016

Evidence for clinical benefits of iron administration

	Patients with CKD not on dialysis	Patients on dialysis
Reduction of congestive heart failure	Limited	Yes
Reduced occurrence of myocardial infarction	Limited	Yes
Improved quality of life	Not studied	Limited
Reduced occurrence of fatigue	Not studied	Limited
Improved cognitive function	Not studied	Limited
ESA dose reduction	Yes	Yes
Reduced blood transfusions	Not studied	Yes

CKD, chronic kidney disease; ESA, erythropoiesis-stimulating agents; RCT, randomized controlled trial.
Limited: data from retrospective, observational studies. Yes: supported by RCT data

Babitt et al. Kidney International 2021 99: 1280-1295

Evidence for increased risk of clinical harm with iron administration

	Patients with CKD not on dialysis	Patients on dialysis
Infections	Limited	No
Cardiovascular events	Limited	No
Diabetes	Limited	Limited
CKD progression	Limited	Not applicable
Anaphylaxis	Minimal	Minimal

CKD, chronic kidney disease; i.v., intravenous; RCT, randomized controlled trial.
No: supported by RCT data. Limited: data from retrospective, observational trials only. Minimal: overall minimal risk for contemporary i.v. iron formulations.

Babitt et al. Kidney International 2021, 99:1280-1295

PIVOTAL
Proactive IV irOn Therapy in haemodiALysis patients

Clinical Lessons from the PIVOTAL Trial

In patients recently started HD, a proactive, high-dose regimen of IV iron (relative to a reactive, low-dose regimen):

- Reduced the risk of the composite primary outcome of death or nonfatal CV events[1]
- Reduced the risk of MI and hospitalization for HF[1,3]
- Reduced ESA dose (19.4%) and transfusion rate (21%)[1]
- Does not cause an increased risk of infection risk[2]
- Does not cause an increased risk of stroke[4]

2025 KDIGO CKD Anemia Guideline (Draft)

Recommendation 2.1: In people with anemia and CKD treated with hemodialysis (CKD G5HD), we suggest initiating iron therapy if ferritin ≤ 500 ng/ml (≤ 500 µg/l) and TSAT ≤30% (2D).

Practice Point 2.2: In people with CKD treated with iron, it is reasonable to withhold iron if ferritin ≥700 ng/ml (≥700 µg/l) or TSAT ≥40%.

2025 KDIGO CKD Anemia Guideline (Draft)

Recommendation 2.2: In people with anemia and CKD G5HD in whom iron therapy is being initiated, we suggest using **IV Iron** rather than oral iron (2D).

Practice Point 2.1: In people with CKD G5HD in whom iron therapy is being initiated, administer **IV Iron using a proactive approach** to maintain stable iron status.

Recommendation 2.4: In people with anemia and **CKD not receiving hemodialysis** in whom iron is initiated, we suggest using either oral or IV iron based on the **person's values and preferences** (2D).

Practice Point 2.3: In people with CKD treated with oral iron, the choice between different formulations and dosing schedules is guided **by cost, individual patient preference, tolerability, and efficacy**.

Practice Point 2.4: In people with CKD treated with intravenous iron, the choice between different formulations is guided **by cost, individual preference, and recommended dosing schedules**.

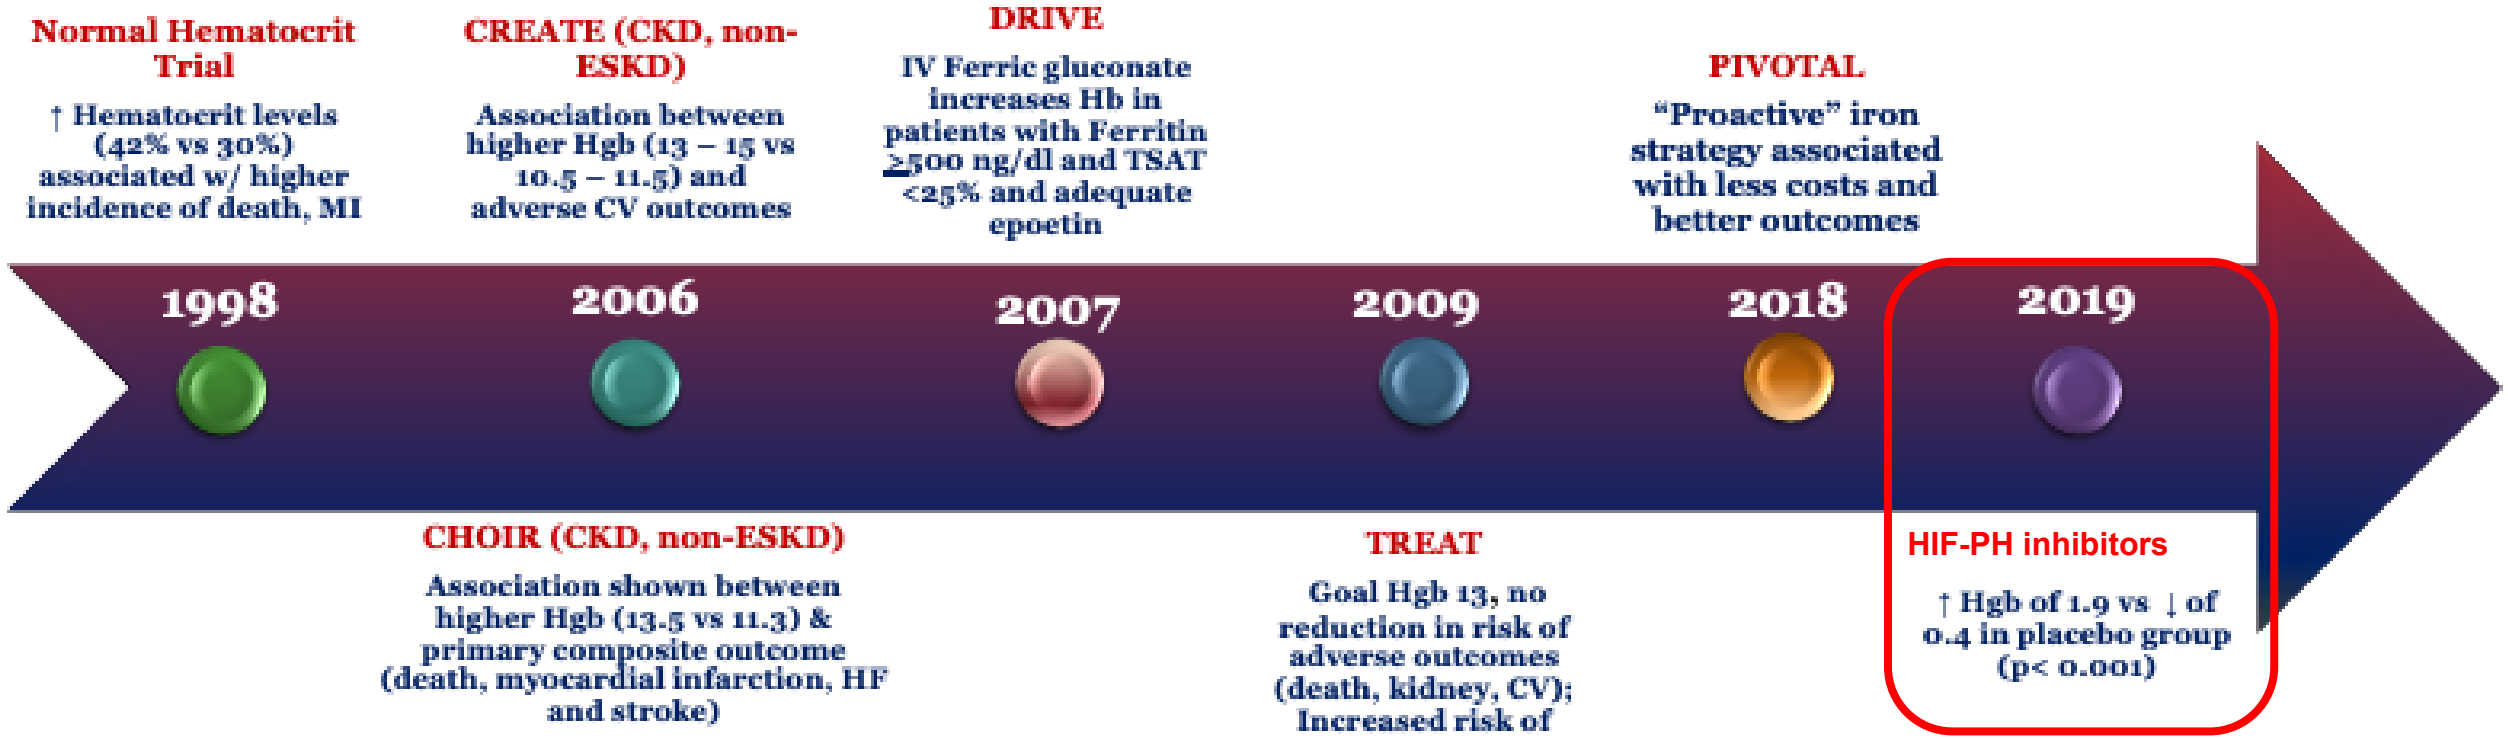
Special considerations in specific populations with CKD

	Specific Considerations
Peritoneal dialysis patients	Both ferric citrate and IV iron administration
Kidney transplant recipients	Caution with IV iron preparations (ferric carboxymaltose, saccharated iron oxide, and iron polymaltose): increased risk of hypophosphatemia
Hypothyroid patients	Caution regarding use of oral iron
Heart failure patients	Correction of iron deficiency with IV iron (ferric carboxymaltose): benefits in terms of intermediate endpoints (6 min walk test, quality of life, NYHA class) and hospitalization. IV iron lowers mortality risk (meta-analysis). Ongoing studies in heart failure patients with preserved ejection fraction, more common in CKD patients not on dialysis
Heart failure patients with reduced ejection fraction	Correction of iron deficiency has benefits independent of anemia
Patients with active infection	Caution about giving IV iron, particularly in those with Gram negative infections
Calciphylaxis patients	Caution in administering IV iron
Liver disease patients	No available data or consensus on iron administration
Children	Understudied area. Absence of RCTs on effects of iron administration on hard clinical outcomes. Results from small open-label and retrospective

CKD, chronic kidney disease; IV, intravenous; NYHA, New York Heart Association; RCTs, randomized controlled trials

Babitt et al. Kidney International 2021, 99: 1280-1295

How are iron kinetics affected in the era of HIF-PHIs ?



- MI: myocardial infarction
- CKD: chronic kidney disease
- ESKD: end-stage kidney disease
- Hgb: hemoglobin (g/dL)
- HF: heart failure
- DM: Diabetes mellitus
- VTE: venous thromboembolism
- HD: hemodialysis
- IV: intravenous

Clinical Kidney Journal

The impacts of hypoxia-inducible factor stabilizers on laboratory parameters and clinical outcomes in chronic kidney disease patients with renal anemia: a systematic review and meta-analysis

Hypoxia-inducible factor (HIF) stabilizer is a novel treatment of anemia in CKD. The present meta-analysis was conducted to extensively evaluate the impacts of HIF stabilizers on laboratory parameters and clinical outcomes.

Methods

Systematic search:
MEDLINE, Scopus, and Cochrane databases

Published and unpublished studies
2010 to March 2022

Outcomes:
- Hemoglobin and iron parameters
- Lipid and inflammatory profiles
- Clinical outcomes

Results

Forty-six studies with 27 338 patients were included in this study

Hemoglobin
Significantly increased Hb levels (MD 0.659 g/dL) compared with the control group (ESA or placebo)

Iron parameters
> Significantly decreased ferritin, TSAT, and hepcidin
> Significantly increased TIBC

Lipid profiles
Significantly decreased TC, LDL, HDL, and TG levels

AKI
RR 1.28 (1.00–1.64)
P = 0.04

MACE
RR 1.00 (0.94–1.07)
P = 0.71

Mortality
RR 0.91 (0.78–1.07)
P = 0.89

Conclusion: The present meta-analysis provided evidence that HIF-stabilizers increased hemoglobin and TIBC levels but reduced hepcidin, ferritin, TSAT, and lipid profiles in CKD patients with renal anemia.

Lab Med 2025. Online ahead of print.

Take Home Message

- Traditional markers such as **ferritin,** and **TSAT** are **insufficient alone** to assess iron stores or predict treatment response.
- **Dynamic biomarkers,** such as **CHr/RET-He, HRC %** or potentially **hepcidin**, to better reflect iron kinetics and the immediate effects of treatment.
- In the era of **HIF-PHIs**, which enhance iron metabolism, the optimal use of iron therapy—including **indications, dosing, and administration route** (IV vs. oral)—may need to be redefined compared with the rHuEPO era.
- A **personalized approach**—tailoring therapy by patient condition, treatment response, and iron metabolism—will be crucial to ensure **safety, efficacy, and sustainability.**

Thanks for your attentions
